Groundwater,
Water Quality.

ABSTRACT

Introduction: The groundwater is the main resource of water. This study aimed to investigate water quality variations in the villages of AqQala in a eleven-year period as well as designing and implementing the Water Quality Index (WQI).

Materials and Methods: In order to investigate water quality variations, the data in the villages of AqQala city was collected in an eleven-year period (2005-2015). Also, according to the research objectives, a sample period in year 2015 was carried out. Samples were measured according to the standard method for examination of water and wastewater. In order to calculate the Groundwater Water Quality Index (GWQI), the Iranian Water Quality Index Software (IWQIS) was used.

Results: Some parameters of water quality, including pH, calcium, magnesium and potassium in all sources, were in standard limit. Some of the parameters were higher than the standard limit, which included turbidity, ammonium, phosphate in all sources and sulfate, chloride, sodium, iron and manganese, silicate and alkalinity in some resource. The results measured by the GWQI index in groundwater resources showed that the groundwater source was not with excellent water quality. About 19.3% of sources had poor qualities and the other sources had good qualities.

Conclusion: The results of water quality over this period showed that some parameters were increased; which leads to water quality reduction. Therefore, comprehensive management of drinking water resources is essential for people's health.

Introduction

Access to safe drinking water sources in many countries of the world, especially in rural areas, is an important subject¹. The groundwater is the main resource of water, which is commonly used for drinking in domestic, irrigation and industrial purposes. The quality of groundwater is importance for domestic and agricultural activities in towns and

villages and small communication²⁻⁶. The quality of groundwater depends on the geologic of an area and mostly contains more mineral contents than the surface water⁷. Furthermore, the hydrologic conditions have a significant role in the groundwater quality change⁷.

Rapid growth of population and industrial activity, unplanned urbanization, improper

management of water body, climatic variability and anthropogenic activities, incomplete treatment of wastewater, improper disposal of municipal and industrial waste are among major factors that affect the quality of drinking water^{2-3, 8}. Several study regarding the groundwater quality done by many authors such as Pandey et al.⁸, Bisht Pandian et al.⁹¹⁰, Rajan and Paneerselvam.¹¹, Thakare et al.¹² and Abinandan et al.². They concluded that inappropriate dumping of solid waste and uncontrolled landfill as well as wastewater and liquid waste, lack of strict enforcement of law and loose governance are causes of deterioration of ground water quality^{2, 8-12}.

Therefore, it is necessary to have a plan for monitoring and managing groundwater and preventing changes in their quality. Various researchers have tried to develop a wide range of WQI for evaluation of groundwater quality; the choice of index depends on the groundwater input parameters and the desired results^{3, 13-17}.

The WQI is introduced as a mathematical instrument to convert the water quality dataset into a single number which represents the water quality level for various applications¹³. The application of water quality indices allows the evaluation and assessment of changes in water quality over time and space and also the evaluation of the efficacy of domestic policies and international strategies designed to protect aquatic resources¹³. Water quality indices are also used for the classification of water³.

Surface water quality indices are different from groundwater quality ones. The most important water quality index is the National Sanitation Foundation Water Quality Index (NSFWQI) number is between 0 and 100, and the closer the index is to 100, the better the quality of water¹⁸. However, in groundwater, conditions are different from surface waters. Different qualitative indices are presented depending on geographical location by different studies¹³⁻¹⁴. For example Ramakrishnaiah et al. presented a groundwater

WQI which was based on 12 parameters, including pH, Total Hardness (TH), Ca^{+2} , Mg^{+2} , HCO_3^- , Cl^- , NO_3^- , SO_4^{-2} , Total Dissolved solids (TDS), Fe^{+2} , Mn^{+2} , and F^- . According to their presented method, values of these 12 parameters should be monitored to calculate the WQI¹⁴. In Iran, Nibizadeh et al. designed the IWQIS for groundwater resources which is in accordance with the standard 1053 of the National Iranian Standards Organization. The numerical value of the index is between 0 and more than 300, the larger the index number indicates the unfavorable quality of the water⁹.

AqQala is one of the cities in Golestan Province. The Golestan providence rural water and wastewater company in the villages of AqQala has served 81 villages. Most of the drinking water sources in AqQala villages are provided from deep wells and the aquifers are not qualitatively and quantitatively normal and standardized, so that most water resources are supplied from the southern parts of the city. Furthermore, aquifers are mainly fine grained sandstone and thus in most of the area, a reservoir of tranquility and reserve has been built. Considering the south-north slope and the location of AqQala in the north of Gorgan city as well as the probability of contamination in AqQala waters to wastewater discharged into wells, this study aimed to investigate the water quality variations in the villages of AqQala in an eleven-Year old period and calculation of the WQI.

Materials and Methods

The studied population is the drinking water resources of the villages covered by AqQala rural water and Wastewater Company, which consists of 31 rural water supply facilities. The rural water supply facilities in AqQala are are show in Table 1 and Figure 1.

Data collection and analysis

In order to investigate the process of changes in water quality, data in the villages of AqQala city during the eleven-year period was taken (2005-2015) from rural water and wastewater company. Also, according to the research objectives, a sample period in year 2015 was carried out in two parts of the low rainy seasons (the first six months) and rainy seasons (the second six months). Parameters were measured according to the standard method for examination of water

and wastewater in the laboratory of rural water and wastewater company¹⁹.

The temperature, pH and Electrical Conductivity (EC) and TDS were measured by Lovibond multiparameter device. Turbidity by 2100P Hach device, and Hardness, alkalinity, chloride were measured by titration. Furthermore sulfate, nitrate, phosphate, ammonium, iron, manganese and fluoride were measured by UV-visible spectrophotometry methods, and Sodium by flame photometer¹⁹.

Calculation of groundwater quality index (GWQI)

To calculate GWQI, IWQIS Software designed by Nabizadeh et al. was used¹³. The software and excel data sheet can be downloaded from:

<http://tums.ac.ir/ajaxplorer/data/public/2941eae5>

0882f1adcb47436ef78c0e16.php?lang=en).

Table 2 shows the criteria parameters, weight factors, and limit values considered for setting up the water quality index. Table 3 reveals the water quality classification based on the IWQIS values.

Table 2: Criteria parameters, weight factors, and limit values considered for setting up IWQIS¹³

Criteria parameters	Value	Limit values
pH*	4	6.5–8.5
Calcium	2	300
Magnesium	2	30
Chloride	3	250
TDS	4	1000
Fluoride	4	1.5
Manganese	4	0.1
Nitrate	5	50
Iron	4	0.3
Sulfate	4	250
Ammonium	3	1.5
Sodium	3	200
Turbidity	4	5

* Except pH and turbidity (NTU), other parameters according to mg/L

Table 3: Water quality classification based on IWQIS values¹³

Water quality index values	Interpretation
< 50	Excellent water quality
50–100	Good water quality
100–200	Poor water quality
200–300	Very poor water quality
> 300	Unsuitable for drinking

Results

The area of AqQala has 31 rural water supply facilities and 61 water wells with a flow rate of 520 L/s. All sources of drinking water in villages are deep wells that are located in the southern part of the city. In this study, the quality of water in the villages of AqQala was evaluated in an eleven-year period (2005-2015) and in 2015 the sampling was carried out twice, consequently in 2015, the GWQI index was calculated with IWQIS.

Some parameters of water quality, including pH, in all sources were in standard range. Some of parameters were higher than the standard range, which included:

Turbidity

The turbidity mean in drinking water sources of AqQala villages in the eleven-year period is shown in Figure 2. The rate of turbidity in some sources was higher than the standard range (5 NTU). In 2015, the amount of turbidity was increased.

Figure 2: Amount of turbidity in the drinking water sources of AqQala villages

Ammonium

Figure 3 reveals the mean of ammonium in drinking water sources of AqQala villages in the eleven-year period. The rate of ammonium in all of

sources is higher than the standard range (1.5 mg/L). From 2008 onwards the amount of ammonium has been increased.

Figure 3: Concentration of ammonium in the drinking water sources of AqQala villages

Phosphate

Figure 4 shows the mean of phosphate in drinking water sources of AqQala villages in the eleven-year period. The rate of phosphate in all of

sources is higher than the standard range (0.2 mg/L). From 2008 onwards the concentration of phosphate has been increased.

Figure 4: Concentration of phosphate in the drinking water sources of AqQala villages

Fluoride

The fluoride mean in the drinking water sources of AqQala villages in the eleven-year periods shown in Figure 5. The rate of fluoride in all of

sources is lower than the standard range (1.4-2.4 mg/L). From 2008 onwards the amount of fluoride has been decreased.

Figure 5: Concentration of fluoride in the drinking water sources of AqQala villages

Total Hardness

Figure 6 shows the mean of total hardness in the drinking water sources of AqQala villages in the eleven-year period. The total hardness of the

groundwater source was very variable (140-576 mg/L). The hardness was related to the amount of sulfate in the groundwater (Figure 6 and 7).

Figure 6: Concentration of total hardness in drinking water sources of AqQala villages

Sulfate

Figure 7 shows the sulfate mean in drinking water sources of AqQala villages in the eleven-year period. The rate of sulfate in all of sources

except source number 31 is lower than the standard range (400 mg/L). The sulfate was related to the amount of total hardness in the groundwater.

Figure 7: Concentration of sulfate in the drinking water sources of AqQala villages

Figure 8: Concentration of nitrate in drinking water sources of AqQala villages

Table 4 shows the GWQI index for drinking water resources in the village of AqQala in 2015. There was no groundwater source with excellent water quality. Sources 6, 9, 10, 15, 30 and 31 had poor qualities and other sources had good qualities.

The results show that all sources of drinking water in the villages are deep wells that are located

in the southern part of the city. Some parameters of water quality, including pH, calcium, magnesium and potassium in all sources, were in standard range. Some of the parameters were higher than the standard range, included turbidity, ammonium, phosphate and sulfate, chloride, sodium, iron and manganese, silicate and alkalinity.

Figure 9: The GWQI Index for drinking water resources in the village of AqQala in 2015

Table 4: The GWQI Index for drinking water resources in the villages of AqQala in 2015

Number of water source	GWQI	Interpretation	Number of water source	GWQI	Interpretation
1	81.3	Good	17	81.62	Good
2	53.66	Good	18	82.75	Good
3	68.29	Good	19	65.96	Good

14	69.39	Good	30	107.51	Poor
15	114.78	Poor	31	113.81	Poor
16	80.8	Good	-	-	-

Discussion

The mean of turbidity in water resources shows that turbidity has increased in some years (Figure 2). The aquifers of AqQala groundwater are mostly fine-grained and have sandstone, and in this area, most of the reservoir has been built for relaxation to solve this problem for all sources of inverter installed, and by installing the inverter device, the sand was reduced, but completely not resolved. The excessive turbidity prevents proper water disinfection and protects microorganisms²⁰.

The rate of ammonium in all of sources is higher than the standard range (1.5 mg/L). From 2008 onwards the amount of ammonium has been increased (figure 3). The high ammonium concentration in all water sources is the probability of entering and infiltration of wastewater from the absorbent wells due to the slope of the area towards AqQala. The study by Doussan et al. shows that high NH_4 concentration is related to the heavy organic load in the river and the mineralization of this organic matter by benthic microflora. Among different mechanisms that influence NH_4 transport and retention in the porous medium, it emerges the sorption by alluvial sediments²¹.

The rate of phosphate in all of sources is higher than the standard range (0.2 mg/L). From 2008 onwards the amount of phosphate has been increased (Figure 4). The reason for decreasing the amount of phosphate in some years is the presence of drought. By the way, agricultural activities and sewage leakage from the wells lead to high level of nutrition²².

The rate of fluoride in all of sources is lower than the standard range (1.4-2.4 mg/L). The main source of fluoride in groundwater is rocks which are rich in fluoride. Fluoride occurs in sellaite, fluorite, cryolite, fluorapatite, apatite, fluormica, biotite, amphibole and several other rocks. Low calcium, high sodium and high bicarbonate are typical of high fluoride groundwater. The other sources for fluoride are infiltration of agricultural runoff containing chemical fertilizers, improper disposal of liquid waste from industries, alumina smelting, cement production and ceramic and brick

firing. Some amount of fluoride is essential for the human body for healthy teeth and bones²³. Due to the low level of fluoride in all drinking water sources in AqQala villages, fluoridation is recommended to prevent the effects of fluoride deficiency on the human health.

The results of this study showed that the concentration of nitrate in the water of AqQala is lower than the standard (Figure8), but the amount of sulfate and hardness is high; since, nitrate can mobilize sulfate from geological pyrite deposits by oxidation of FeS_x in the aquifer, leading to a decrease of nitrate and an increase of groundwater sulphate concentrations²². Some parameters such as sulfate and phosphate have decreased from 2008 to 2013 that is the reason for decreasing the concentration of this parameter in the presence of drought. Although these parameters are reducing, their values in some sources are higher than the standard.

The results measured by the GWQI index in groundwater resources showed that the groundwater source was not with excellent water quality. About 19.3% of sources had poor qualities and the other ones had good qualities. As well as some sources (such as 5, 11) had near poor qualities. The results of water quality over the eleven-year period have shown that water quality is reduction. Therefore, comprehensive management of drinking water resources is essential for people's health.

Conclusion

The results of the eleven-year drinking water quality in villages in the city of AqQala indicate that in some cases, such as color, nitrite and nitrate, water quality has improved in recent years compared with previous years due to improved sanitary conditions and sanitation of wastewater. However, some parameters have increased in recent years, including ammonium, phosphate, chlorine, sulfate, hardness and silicate, which indicate the probability of wastewater penetration with regard to the slope of the region from north to south, which requires more extensive studies.

The results of chemical quality showed that all drinking water sources have hard and very hard water. There is also a direct relationship between the degree of hardness and the amount of water sulfate. The amount of fluoride in all drinking water sources is below the standard level. To prevent dental caries in children and adolescents, adding fluoride to water or supplying it with other sources is essential. Considering the limited water resources and the reduction of the quality of resources and the increase of some parameters such as sulfate, hardness, ammonium, water resources management is necessary to prevent the quality reduction and its impact on the health of people and community.
